

DASHBOARD FOR A MINE ESG PERFORMANCE 2025

Executive ESG Performance Summary – 2025

The most significant positive development is the reduction in GHG emissions. Energy and water performance remained stable, while female representation showed modest improvement. However, declining recycling performance and a slight reduction in local employment indicate areas requiring management attention. Management should therefore prioritise maintaining the downward trend in GHG emissions, investigate the decline in recycling performance, identify opportunities to improve energy and water efficiency, and continue monitoring workforce diversity and local employment.

Important consideration: Environmental indicators in the current dataset are not normalised against coal production. As a result, reductions in energy, water or GHG emissions may be influenced by changes in production levels. Future ESG reporting should include indicators such as **tCO₂e per tonne of coal produced, kWh per tonne, kL of water per tonne and waste per tonne produced** to provide a stronger assessment of operational ESG efficiency.
